

Resource management

(1) process management

|| → program in execution

↳ program + execution environment { registers

know from running → waiting state

Synchronization between child & parent

waiting for resources to be available
State transition

new

ready
has res except CPU

valuable (not idle) if/when scheduling algo

CPU

wait for IO

I/O time

(2) PCB (process control block) PD (process descriptor)

child tells parent 'exit'

Process ID, register contents, program counter, child processes

(3) CPU scheduling

(4) process synchronization

Critical section problem,

(5) process deadlock handling

(6) process communication

uses buffer producer consumer
CPU ↔ printer

3 ways: signals (UNIX/Linux)

shared memory setup variable in memory

message passing handled by kernel

memory management

(1) memory space allocation/deallocation

(2) trace of free and allocated memory space first fit, best worst, next fit

(3) virtual memory management (paging, segmentation, or both)

32-bit

$$2^{32} \text{ bytes} = \boxed{4 \text{ GB}}$$

2^{64} bytes

File management

mass-storage management

(1) storage allocation/deallocation

(2) disk scheduling

(3) free storage space management

protection & security

Can't access resources directly

System calls used to access system resources

fork() , execve , wait , exit , open() , read() , write() , pipe() ,
↑
triggered to kernel
UNIX/Linux approach
↓
invoked by parent
child
open file
result has to exist
if doesn't, give parameters
file descriptor (pointer pointing to location of file)
↑
saves time
Pipe
a/b
otherwise default output
file pointer = internal pointer used to get next character

$\text{CreateProcess(...)}$ ← library function call
Windows
more flexible

API (Application Programming Interface)

Types of OS

(1) batch systems - program treated as a batch ^{one thing}

JCL (Job Control Language)

everything given to OS at a time
 $F1 \rightarrow C1 \rightarrow F2 \rightarrow F3$
must wait for OS to complete once
Setup time is the bottleneck
turnaround time = time when submit until everything comes back

solution: Common problem

Multi programming - put multiple programs in memory / good for time sharing systems

(2)

(CPU can be interleaved)
variety between processes

response time

(3) real time systems - microprocessor

3 types of info: text, audio, video processor by

Soft RT systems - if miss 1-2 frames, it's fine

Hard RT systems - must react instantly, can't miss frame

Handheld systems
